Hiding a Secret Information in Image Using Gravitational Search Algorithm

Omar Younis Abdulhameed

Abstract

Information is so important thing to us. Therefore, protecting the data by using information concealing techniques have become interest in the most applications. This paper proposed new algorithm is gravitational search algorithm in order to determine best locations in a carrier image (color image) that will be used to conceal secret information by effective and efficient method, this paper propose an effective and efficient method for determining best hiding locations in a carrier (colored image) by using gravitational search algorithm. The gravitational search algorithm is depended on gravity rules that concerns the fact that an object with mass attracts one another. The PSNR of the stego image1 and stego image2 are 72.55 and 71.21 respectively.

Keywords: Gravitational Search algorithm, Information hiding, Cover image, Stego Image, secret information, PSNR.
Hiding a Secret Information in Image Using Gravitational Search Algorithm

Omar Younis Abdulhameed

Abstract

The information is important for us. Therefore, the protection of information using information hiding techniques became important in many application fields. This research proposes a method and a powerful technique to determine the best hiding positions in the color carrier image using the gravitational search algorithm. The gravitational search algorithm is based on the laws of gravity that two bodies with mass attract each other. The ratio of the first and second images noise level is 72.55 and 71.21 respectively. The results show that the proposed method is effective and can resist some attacks.

Keywords: Gravitational Search Algorithm, Information Hiding, Color Image, Hidden Image, Secret Information, Quality Measurement of Image.

Introduction

In recent years and with quick growth of internet applications, almost everything has become digitally. The information that are transmit electronically is growing extremely [1]. Unauthorized user who may attempt to overhear this conversation can either tamper with this information to change its original meaning or it can try to listen to the message with intention to decode it and use it to his/her advantage. Both these attacks violated the confidentiality and integrity of the message passed [2]. Steganography (information hiding) is a system to protect secret data in the carrier media. The goal of the system is not only to ensure that the secret message sent in secret, but make the transmitter process is invisible, it is the art of the invisible transmitter process and provide denial in the policy of confidential communications [3]. The host media must include the most of its original content. The hidden media should be concealed with certain robustness so that the secret can resist certain attack [4].

Steganography Process

The term steganography is come from Greek and indicate to “covered writing”. A Steganography technique contains 3 parts: cover-image (which used to hides the secret data), the secret data and the stega-image (which is the carrier image with secret data concealed in
Hiding a Secret Information in Image Using Gravitational Search Algorithm

Omar Younis Abdulhameed

Majority of the data and information that hide are image, therefore image steganography indicate to the process of setting confidential data in the image by the sender and is sent to the receiver, the receiver then extract the hidden information from the stego image by using stego key (key provided by sender) [6]. The major aim is that the confidential data will not be observed if unauthorized user attempts to intercept the cover media. The operation of extract confidential data from the carrier image is easy because it is mirrored of the concealment process, where the confidential data is detected at the finish. The figure (1) display the process of steganography system. The result of the steganographic system is the stego message. The carrier media should be as same data type as stego image, but the secret data may be in any data type. [7]

Gravitational Search Algorithm (GSA)

GSA was introduced by Rashedi and is proposed to solve optimization problems and to enhance the efficiency in the reconnaissance and investment abilities of population based algorithm, depend on the rules of gravity. The population-based heuristic algorithm is based on the law of gravity and mass interactions. The gravity force causes a global movement where all objects move towards other objects with heavier masses. The slow movement of heavier masses guarantees the exploitation step of the algorithm and corresponds to good solutions [8]. which says that “every massive particle in the universe attracts other massive one with a force that is directly proportional to the product of their masses and inversely proportional to the square of the distance between them” [9]:

\[ F = \frac{G \cdot M_1 \cdot M_2}{R^2} \] \hspace{1cm} (1)
in which $M_1$ and $M_2$ are two particles, $R_2$ is the distance between them, $G$ is a gravitational constant and $F$ is the magnitude of the gravitational force. The $G$ is constant:

$$G(t) = G(t_0) \left( \frac{t_0}{t} \right)^\beta, \beta < 1,$$

(2)

in which $G(t)$ is the value ofgravitational constant at time $t$, and $G(t_0)$ is the value of the gravitational constant at the time of the “creation of the universe” that is being considered.

Newton’s second law says that when a force $f$ is applied to a mass, its acceleration $A$ only depends on the force and its mass $m$:

$$A = \frac{F}{M}.$$

(3)

Based on above definitions, the (GSA), known as:

Let $X = [x_1, x_2, \ldots, x_m]$ be an universe with $m$ masses, such that $x_i$ belong to $R_n$, where $i=1,2,\ldots,m$, $X$ represent the positions. One can define, at a specific time $t$, the force acting on mass $i$ from mass $j$ in the $d^{th}$ dimension as following:

$$F_{ij}^d = G(t) \left( \frac{M_i(t) M_j(t)}{R_{ij}^d + e} \right) (x_{jd}(t) - x_{id}(t))$$

(4)

Where $R_{ij}(t)$ is the Euclidean distance between masses $i$ and $j$, and $e$ is a small constant. In order to give a stochastic behavior to GSA, assume the total force that acts on agent $i$ in a dimension $d$ as a randomly weighted sum of the forces exerted from other agents:

$$F_{id}^d(t) = \sum_{j \neq i} y_j F_{ij}^d(t)$$

(5)

In which $y_j$ denotes a randomly generated number between 0 and 1. The acceleration of mass $I$ at time $t$ and dimension $d$ is given by:

$$a_{id}^d(t) = \frac{F_{id}^d(t)}{M_i(t)}$$

(6)

In which the mass $M_i$ is calculated as follows:

$$M_i(t) = \frac{q_i(t)}{\sum_{j=1}^{m} q_j(t)}$$

(7)

With

$$q_i(t) = (f_i(t) - w(t))/b(t) - w(t)$$

(8)

the term $w(t)$ and $b(t)$ mean, respectively, the masses with worst and best fitness value, where the value of $w(t)$ is worst (min) fitness for all agents at each iteration and $b(t)$ is best(max) fitness for all agents at each iteration. The term $f_i(t)$ denotes the fitness value of mass $i$. Hence, equation (5) is rewritten as:

$$F_{id}^d(t) = \sum_{j \in k, j \neq i} Y_j F_{ij}^d(t)$$

(9)
The equations (10) and (11) used for updating velocity and position respectively

$$V_{d_i}(t+1) = y_j v_{d_i}(t) + a_{d_i}(t) \hspace{1cm} \text{.................................................................(10)}$$

$$X_{d_i}(t+1) = x_{d_i}(t) + v_{d_i}(t+1) \hspace{1cm} \text{.................................................................(11)}$$

**Proposed Method**

1. **Applied GSA**

The main idea is to use the GSA to determine the optimal locations in the carrier image, the carrier image is (128*128) pixel and it is represented as array of two dimension to the GSA algorithm, where the cover image is divided into 4 imaginary parts (part1, part2, part3, part4) as shown in figure (2), and each part with size (32*32) and the center of each part is the point (16,16) , then the fitness is calculated for every location of the image and calculated by using

function \( Z(s) = z(s)/z(sm) \) \hspace{1cm} \text{..................................................................................(12)}

where \( z(s) \) is fitness of the object (s), and \( z(sm) \) is total fitness of all objects, where the fitness of the object (s) = value (s) = (pixel value), then GS algorithm according to algorithm number (1) is applied parallel on the four sections and block diagram of applied GS algorithm to find the best locations is shown in figure (3)

![Figure 2: Four imaginary sections of image](image-url)
Hiding a Secret Information in Image Using Gravitational Search Algorithm

Omar Younis Abdulhameed

Algorithm 1: Applied GSA to find Optimal Locations of The Carrier Image

| Input: | Initialization of static parameters: iteration=300, G=0.0048, yi=0.5, carrier image =128*128 pixel. |
| Output: | Determined locations that visited by (GSA). |

Begin

Step 1: Divided the carrier image into four imaginary section equally.
Step 2: Calculate the fitness function for each object (x) in the search space by using Eq.(12).
Step 3: Generate initial position (fac) of 4 agents at the center of each section, and the value of agent=pixel value
Step 4: For each section do
(a) Calculate the value of mass (m) for each object (x), where mass(m)=fitness object(x),
(b) Calculate the value of F between every two objects according to Eq. (1).
(c) Evaluate the velocity and position for each agent in the section according to Eq. (10) and Eq.(11) where yi =0.5, vdi= value of the agent’s fitness.
(d) Comparing current agent fitness value (fac) with local agents fitness value (ba).
(e) If (fac) > (ba) then change the location of (fac) with (upper or lower or right or left).
(f) If (fac) < (ba) then fac = max(ba).
(g) put max(ba) location in the list (L) to be the best location without repetition.
(h) Update velocity according to Eq.(10) and position according to Eq.(11).
(i) If number of iteration ≠300 then go step 4(c).

End
Hiding a Secret Information in Image Using Gravitational Search Algorithm

Figure 3: Block Diagram of Hiding Secret Information Using GSA
B. Hiding Process

The secret information is converted into its binary values and equals to 3600 bits, which represent confidential information. Also, the values of the 1200 best locations of the cover image (128x128 pixels) selected by GS algorithm are split into three basic values that represent the basic three colors (Red, Green, Blue). Then, it is converted to the binary values, and the color of each location can hide three bits in its least significant bit. Therefore, each location will hide 3 bits from the secret information. Figure (4) shows the diagram of the hidden process.

Figure (5) show two cover images with and without the locations that are selected by GS algorithm. It is noted that the algorithm was applied to four sections of the image where the locations chosen by the algorithm were colored in green, figure (6) and figure (7) show the relationship between the locations and its values for stego image (1) and stego image (2) respectively and for the upper right section only, also the locations selected are random (non sequential) and have a large fitness which increases security factor and reduces the possibility of image confusion.

Conclusions

This work presents a successful GS algorithm, because of:

1. The time taken for the embedding process is 2.5 seconds which is very little time as shown in table (3).
2. Experimental results as observed in table (4) show high PSNR value and low MSE value for reconstructed images, that refers to good quality of reconstructed image.
3. Increase security, figure (6), figure (7) and figure (8) shown the selected locations are random (not sequential).
4. Provides speed because it works in an organized and efficient fashion.
